Exploring the Transient Universe with *Roman*
February 2022

Past: Used machine learning to find
Superluminous Supernovae

Present: Applying methods to
Tidal Disruption Events

Future: Predictions for transients with
Roman

Superluminous Supernovae

They were designated as **superluminous** if brighter than -21 mag

Now, they are classified by their **spectra**

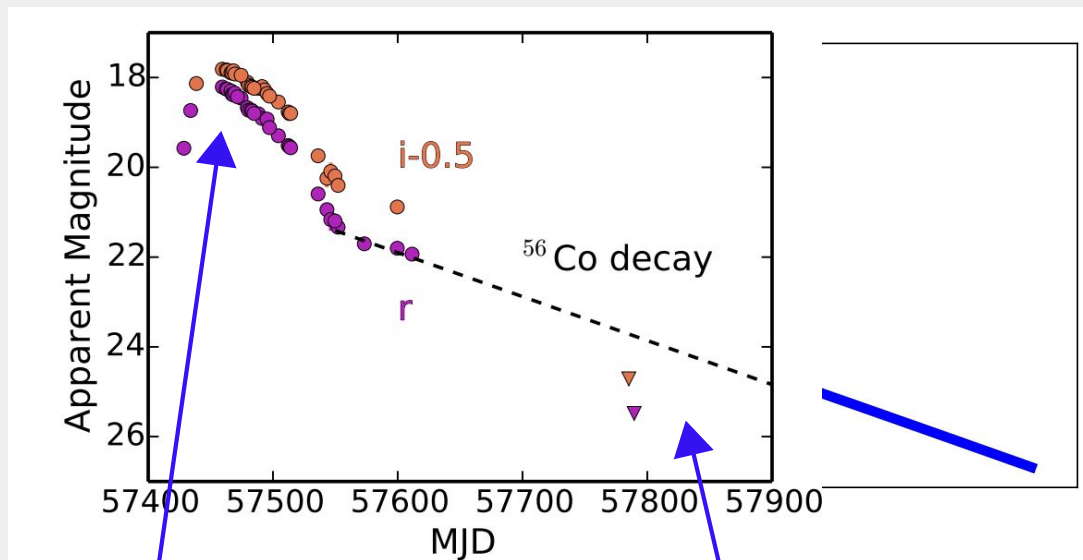

What makes them so bright?

Normal SNe are powered by
radioactive decay

What makes them so bright?

28 Msun of Nickel to power the peak

Limit of < 0.35 Msun of Nickel

Central Engine

Kasen & Bildsten 2010

Metzger+ 2015

Central Engine

Mazzali+ 2016

Central Engine

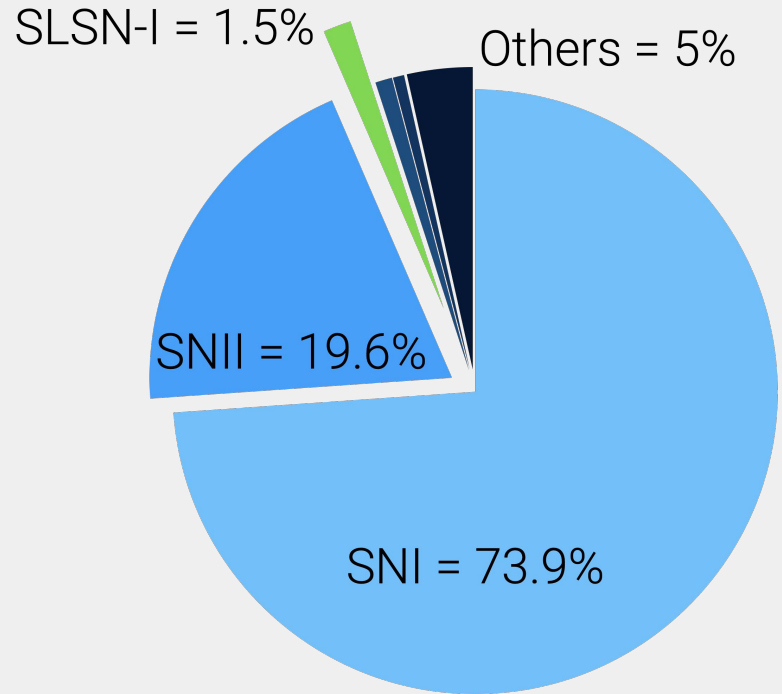

Nicholl+ 2017

How do we find them?

Unbiased Surveys

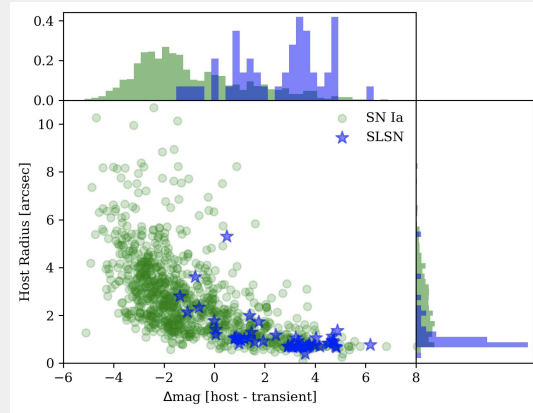

ZTF ~ 1500 Transients / month

FLEET Algorithm

Finding Luminous and Exotic Extragalactic Transients

Features

1. Width of the light curve
2. Time to peak
3. Color
4. Normalized host separation

**No Redshift
Needed**

Predictions

1500 Transients = 23 SLSN-I = 5 Candidates = 4 SLSN-I / Month

50x better than random selection

Results

37 SLSNe found worldwide since Nov 2020

13 classified by FLEET

$P(\text{SLSN-I}) > 50\% = (18/37) \sim 50\%$ of all SLSN-I recovered

Tidal Disruption Events

Tidal Disruption Events

S. Gezari, Physics Today.

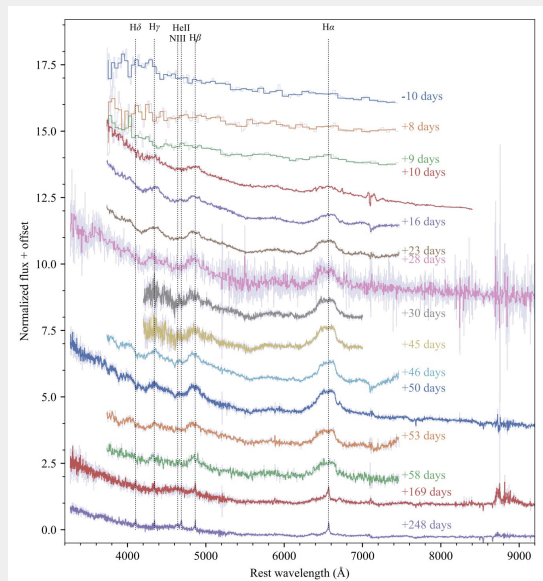

Blanchard+ 2017

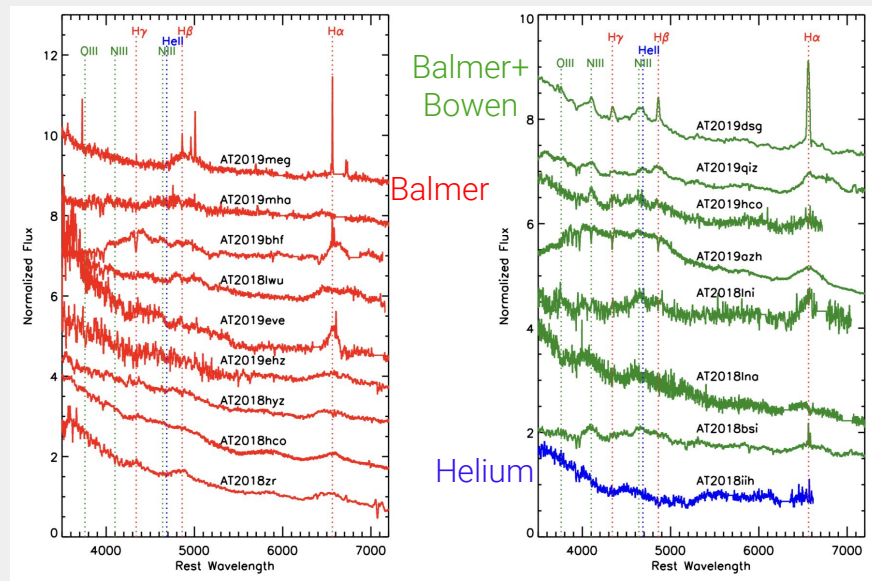

Tidal Disruption Events

Arcavi+ 2014

Nicholl+ 2019

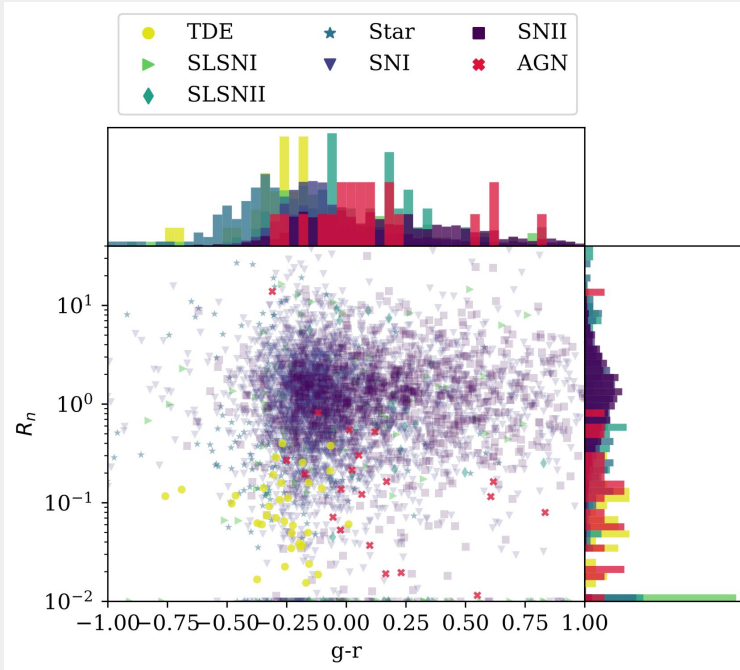

Van Velzen+ 2020

Wide diversity of features
Only ~40 well characterized TDEs

Tidal Disruption Events

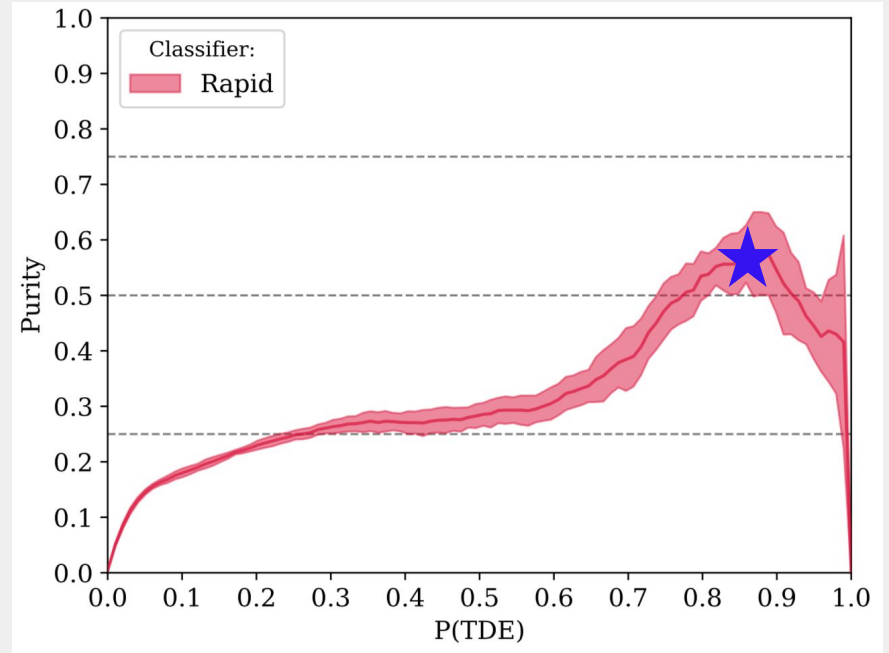

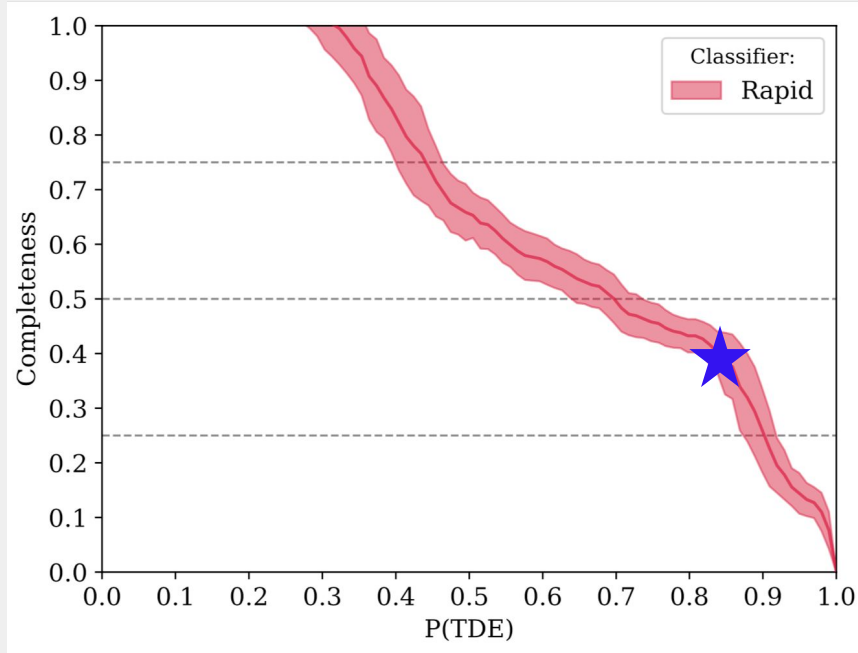

Features

- Color
- Rise time
- Light curve duration
- Host color
- Host separation

TDEs are blue and nuclear

Tidal Disruption Events

1500 Transients = 8 TDEs = 3 Candidates = 1-2 TDEs / Month

100x better than random selection

Roman Survey

NASA, Rose+, Supernovae SIT

High Latitude Time
Domain Survey

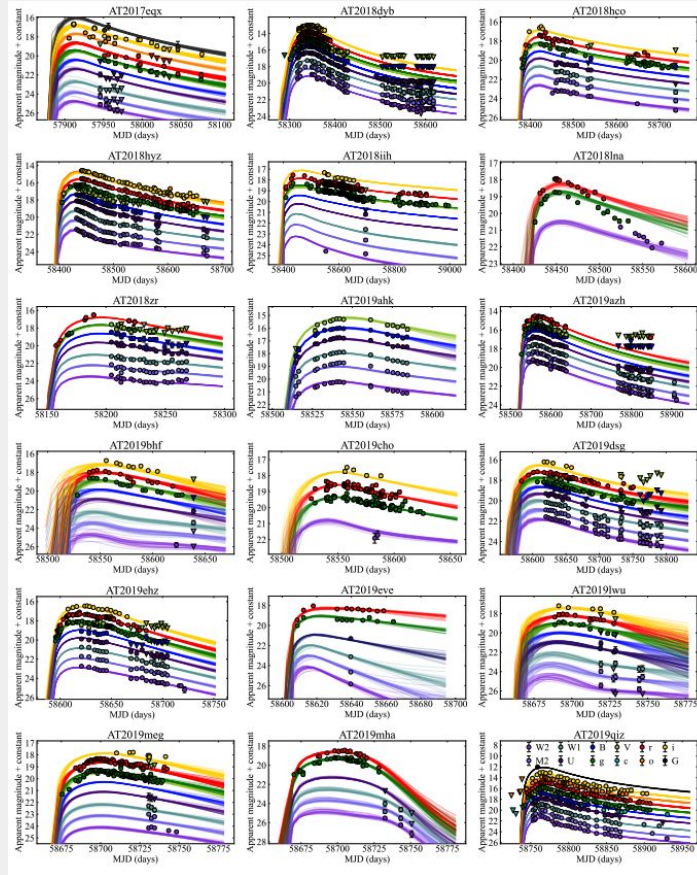

16 sq. deg.
5 day cadence
2 year duration
6 filters (4 per mode)

Roman Survey

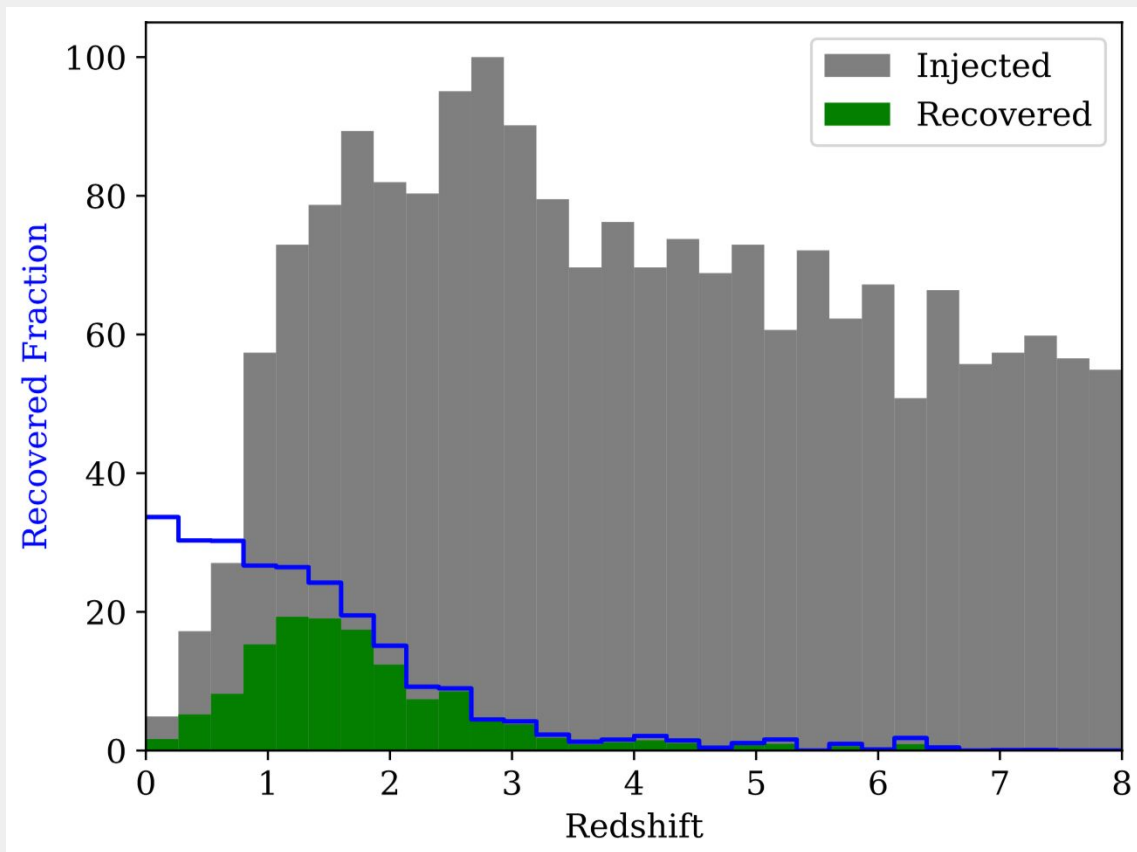

Wide mode
+
Deep mode

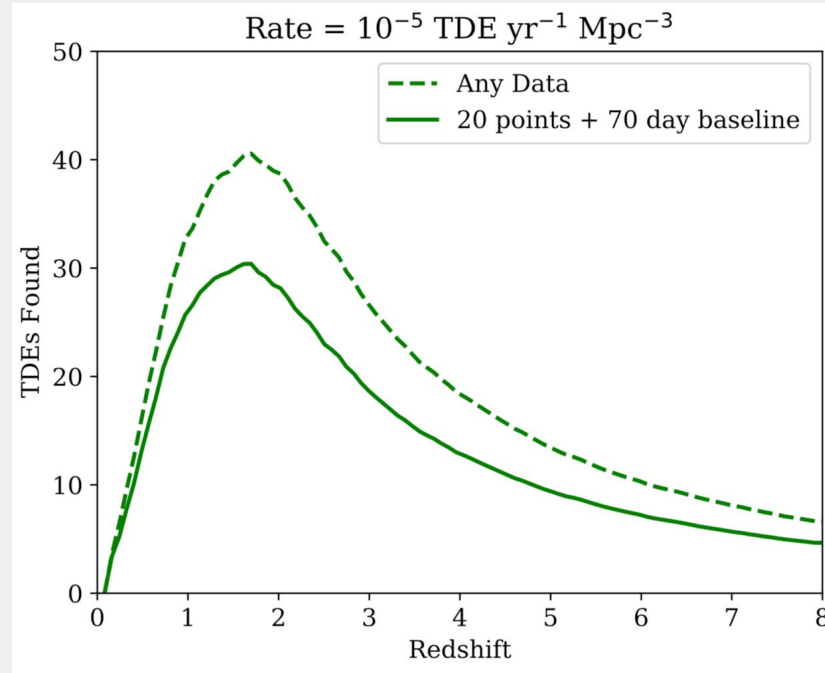

Roman Survey

TDEs from *Roman*

Applications to *Roman*

FLEET: $30 \times (0.4 \text{ Completeness}) \times (0.6 \text{ Purity}) = 7 \text{ TDEs / year}$
